#### 10 Exercises and Problems

Vibration problems lead to differential equations with solutions that in time, typically in a damped or undamped sinusoidal fashion. Such solut certain demands on the numerical methods compared to other phenomen solutions are monotone. Both the frequency and amplitude of the osci need to be accurately handled by the numerical schemes. Most of the reand specific building blocks introduced in the fortcoming text can be to construct sound methods for partial differential equations of wave namultiple spatial dimensions.

#### 1 Finite difference discretization

Much of the numerical challenges with computing oscillatory solutions is and PDEs can be captured by the very simple ODE u'' + u = 0 a

therefore the starting point for method development, implementation, and nalysis.

#### .1 A basic model for vibrations

system that vibrates without damping and external forcing can be described y ODE problem

$$u'' + \omega^2 u = 0$$
,  $u(0) = I$ ,  $u'(0) = 0$ ,  $t \in (0, T]$ . (1)

Lere,  $\omega$  and I are given constants. The exact solution of (1) is

$$u(t) = I\cos(\omega t). \tag{2}$$

hat is, u oscillates with constant amplitude I and angular frequency  $\omega$ . The presponding period of oscillations (i.e., the time between two neighboring eaks in the cosine function) is  $P=2\pi/\omega$ . The number of periods per second  $f=\omega/(2\pi)$  and measured in the unit Hz. Both f and  $\omega$  are referred to as equency, but  $\omega$  may be more precisely named angular frequency, measured in ad/s.

In vibrating mechanical systems modeled by (1), u(t) very often represents a osition or a displacement of a particular point in the system. The derivative u'(t) nen has the interpretation of the point's velocity, and u''(t) is the associated occleration. The model (1) is not only applicable to vibrating mechanical vstems, but also to oscillations in electrical circuits.

#### .2 A centered finite difference scheme

o formulate a finite difference method for the model problem (1) we follow the sur steps from Section ??in [1].

tep 1: Discretizing the domain. The domain is discretized by introducing uniformly partitioned time mesh in the present problem. The points in the resh are hence  $t_n = n\Delta t, \ n = 0, 1, \dots, N_t$ , where  $\Delta t = T/N_t$  is the constant right of the time steps. We introduce a mesh function  $u^n$  for  $n = 0, 1, \dots, N_t$ , hich approximates the exact solution at the mesh points. The mesh function ill be computed from algebraic equations derived from the differential equation roblem.

**tep 2: Fulfilling the equation at discrete time points.** The ODE is to e satisfied at each mesh point:

$$u''(t_n) + \omega^2 u(t_n) = 0, \quad n = 1, \dots, N_t.$$
 (3)

Step 3: Replacing derivatives by finite differences. The de  $u''(t_n)$  is to be replaced by a finite difference approximation. A common order accurate approximation to the second-order derivative is

$$u''(t_n) \approx \frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2}$$
.

Inserting (4) in (3) yields

$$\frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2} = -\omega^2 u^n \,.$$

We also need to replace the derivative in the initial condition by difference. Here we choose a centered difference, whose accuracy is sin the centered difference we used for u'':

$$\frac{u^1 - u^{-1}}{2\Delta t} = 0.$$

Step 4: Formulating a recursive algorithm. To formulate the continuous algorithm, we assume that we have already computed  $u^{n-1}$  and that  $u^{n+1}$  is the unknown value, which we can readily solve for:

$$u^{n+1} = 2u^n - u^{n-1} - \Delta t^2 \omega^2 u^n$$
.

The computational algorithm is simply to apply (7) successively for  $1, 2, \ldots, N_t - 1$ . This numerical scheme sometimes goes under the name Stamethod or Verlet integration<sup>1</sup>.

Computing the first step. We observe that (7) cannot be used fo since the computation of  $u^1$  then involves the undefined value  $u^{-1}$  at t. The discretization of the initial condition then come to rescue: (6)  $u^{-1} = u^1$  and this relation can be combined with (7) for n = 1 to yield for  $u^1$ :

$$u^1 = 2u^0 - u^1 - \Delta t^2 \omega^2 u^0,$$

which reduces to

$$u^{1} = u^{0} - \frac{1}{2}\Delta t^{2}\omega^{2}u^{0}.$$

Exercise 5 asks you to perform an alternative derivation and also to ge the initial condition to  $u'(0) = V \neq 0$ .

<sup>&</sup>lt;sup>1</sup>http://en.wikipedia.org/wiki/Verlet\_integration

'he computational algorithm. The steps for solving (1) becomes

- 1.  $u^0 = I$
- 2. compute  $u^1$  from (8)
- 3. for  $n = 1, 2, \dots, N_t 1$ :
  - (a) compute  $u^{n+1}$  from (7)

he algorithm is more precisely expressed directly in Python:

```
; = linspace(0, T, Nt+1) # mesh points in time
it = t[1] - t[0] # constant time step
i = zeros(Nt+1) # solution

i[0] = I
i[1] = u[0] - 0.5*dt**2*w**2*u[0]
ior n in range(1, Nt):
    u[n+1] = 2*u[n] - u[n-1] - dt**2*w**2*u[n]
```

#### Remark.

In the code, we use  ${\tt w}$  as the symbol for  $\omega$ . The reason is that this author prefers  ${\tt w}$  for readability and comparison with the mathematical  $\omega$  instead of the full word omega as variable name.

**Operator notation.** We may write the scheme using the compact difference otation (see Section ??in [1]). The difference (4) has the operator notation  $\partial_t D_t u$ <sup>n</sup> such that we can write:

$$[D_t D_t u + \omega^2 u = 0]^n. (9)$$

ote that  $[D_t D_t u]^n$  means applying a central difference with step  $\Delta t/2$  twice:

$$[D_t(D_t u)]^n = \frac{[D_t u]^{n+\frac{1}{2}} - [D_t u]^{n-\frac{1}{2}}}{\Delta t}$$

hich is written out as

$$\frac{1}{\Delta t} \left( \frac{u^{n+1}-u^n}{\Delta t} - \frac{u^n-u^{n-1}}{\Delta t} \right) = \frac{u^{n+1}-2u^n+u^{n-1}}{\Delta t^2} \,.$$

The discretization of initial conditions can in the operator notation be expressed as

$$[u=I]^0, \quad [D_{2t}u=0]^0, \tag{10}$$

here the operator  $[D_{2t}u]^n$  is defined as

$$[D_{2t}u]^n = \frac{u^{n+1} - u^{n-1}}{2\Delta t} \,. \tag{11}$$

#### 2 Implementation

#### 2.1 Making a solver function

The algorithm from the previous section is readily translated to a  $\alpha$  Python function for computing (returning)  $u^0, u^1, \ldots, u^{N_t}$  and  $t_0, t_1$ , given the input  $I, \omega, \Delta t$ , and T:

```
from numpy import *
from matplotlib.pyplot import *
from vib_empirical_analysis import minmax, periods, amplitudes

def solver(I, w, dt, T):
    """
    Solve u'' + w**2*u = 0 for t in (0,T], u(0)=I and u'(0)=0,
    by a central finite difference method with time step dt.
    """
    dt = float(dt)
    Nt = int(round(T/dt))
    u = zeros(Nt+1)
    t = linspace(0, Nt*dt, Nt+1)

u[0] = I
    u[1] = u[0] - 0.5*dt**2*w**2*u[0]
    for n in range(1, Nt):
        u[n+1] = 2*u[n] - u[n-1] - dt**2*w**2*u[n]
    return u, t
```

A function for plotting the numerical and the exact solution is also cor to have:

```
def u exact(t, I, w):
    return I*cos(w*t)
def visualize(u, t, I, w):
    plot(t, u, 'r--o')
    t_fine = linspace(0, t[-1], 1001) # very fine mesh for u_e
    u_e = u_exact(t_fine, I, w)
    hold('on')
    plot(t_fine, u_e, 'b-')
    legend(['numerical', 'exact'], loc='upper left')
    xlabel('t')
    ylabel('u')
    dt = t[1] - t[0]
    title('dt=%g' % dt)
    umin = 1.2*u.min(); umax = -umin
    axis([t[0], t[-1], umin, umax])
    savefig('vib1.png')
    savefig('vib1.pdf')
    savefig('vib1.eps')
```

A corresponding main program calling these functions for a simulation of number of periods (num periods) may take the form

```
[ = 1
v = 2*pi
it = 0.05
num_periods = 5
> = 2*pi/w  # one period
[ = P*num_periods
1, t = solver(I, w, dt, T)
risualize(u, t, I, w, dt)
```

Adjusting some of the input parameters on the command line can be handy. ere is a code segment using the ArgumentParser tool in the argparse module define option value (-option value) pairs on the command line:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--I', type=float, default=1.0)
parser.add_argument('--w', type=float, default=2*pi)
parser.add_argument('--dt', type=float, default=0.05)
parser.add_argument('--num_periods', type=int, default=5)
i = parser.parse_args()
[, w, dt, num_periods = a.I, a.w, a.dt, a.num_periods
```

A typical execution goes like

```
erminal> python vib_undamped.py --num_periods 20 --dt 0.1
```

**Computing** u'. In mechanical vibration applications one is often interested a computing the velocity v(t) = u'(t) after u(t) has been computed. This can e done by a central difference,

$$v(t_n) = u'(t_n) \approx v^n = \frac{u^{n+1} - u^{n-1}}{2\Delta t} = [D_{2t}u]^n.$$
 (12)

his formula applies for all inner mesh points,  $n = 1, ..., N_t - 1$ . For n = 0 we ave that v(0) is given by the initial condition on u'(0), and for  $n = N_t$  we can se a one-sided, backward difference:  $v^n = [D_t^- u]^n$ .

Appropriate vectorized Python code becomes

#### .2 Verification

**fanual calculation.** The simplest type of verification, which is also instructed for understanding the algorithm, is to compute  $u^1$ ,  $u^2$ , and  $u^3$  with the aid a calculator and make a function for comparing these results with those from

the solver function. We refer to the  $test\_three\_steps$  function in  $vib\_undamped.py^2$  for details.

Testing very simple solutions. Constructing test problems where the solution is constant or linear helps initial debugging and verification expects any reasonable numerical method to reproduce such solutions to a precision. Second-order accurate methods will often also reproduce a quad solution. Here  $[D_tD_tt^2]^n=2$ , which is the exact result. A solution u=t to  $u''+\omega^2u=2+(\omega t)^2\neq 0$ . We must therefore add a source in the equivalent  $u''+\omega^2u=f$  to allow a solution  $u=t^2$  for  $f=(\omega t)^2$ . By simple in we can show that the mesh function  $u^n=t^2_n$  is also a solution of the equations. Problem 1 asks you to carry out all details with showing the and quadratic solutions are solutions of the discrete equations. Such respectively useful for debugging and verification.

Checking convergence rates. Empirical computation of convergence as explained in Section ??in [1], yields a good method for verification function below

- performs m simulations with halved time steps:  $2^{-i}\Delta t$ ,  $i=0,\ldots$
- computes the  $L^2$  norm of the error,  $E = \sqrt{2^{-i}\Delta t \sum_{n=0}^{N_t-1} (u^n u_e)}$  each case,
- estimates the convergence rates  $r_i$  based on two consecutive expe  $(\Delta t_{i-1}, E_{i-1})$  and  $(\Delta t_i, E_i)$ , assuming  $E_i = C\Delta t_i^{r_i}$  and  $E_{i-1} = F_{i-1}$  From these equations it follows that  $r_{i-1} = \ln(E_{i-1}/E_i)/\ln(\Delta t_{i-1})$  for i = 1, ..., m-1.

All the implementational details appear below.

```
def convergence_rates(m, solver_function, num_periods=8):
    Return m-1 empirical estimates of the convergence rate
    based on m simulations, where the time step is halved
    for each simulation.
    w = 0.35; I = 0.3
    dt = 2*pi/w/30 \# 30 time step per period 2*pi/w
    T = 2*pi/w*num_periods
    dt_values = []
    E_{values} = []
    for i in range(m):
        u, t = solver_function(I, w, dt, T)
        u e = u exact(t, I, w)
        E = sqrt(dt*sum((u_e-u)**2))
        dt_values.append(dt)
        E_values.append(E)
        dt = dt/2
```

<sup>&</sup>lt;sup>2</sup>http://tinyurl.com/nm5587k/vib/vib\_undamped.py

```
r = [log(E_values[i-1]/E_values[i])/
    log(dt_values[i-1]/dt_values[i])
    for i in range(1, m, 1)]
return r
```

he returned  $\mathbf{r}$  list has its values equal to 2.00, which is in excellent agreement ith what is expected from the second-order finite difference approximation  $\mathcal{D}_t \mathcal{D}_t u$ <sup>n</sup> and other theoretical measures of the error in the numerical method. he final  $\mathbf{r}[-1]$  value is a good candidate for a unit test:

```
lef test_convergence_rates():
    r = convergence_rates(m=5, solver_function=solver, num_periods=8)
    # Accept rate to 1 decimal place
    nt.assert_almost_equal(r[-1], 2.0, places=1)
```

he complete code appears in the file vib\_undamped.py.

#### Long time simulations

igure 1 shows a comparison of the exact and numerical solution for  $\Delta t = 0.1, 0.05$  and  $w = 2\pi$ . From the plot we make the following observations:

- The numerical solution seems to have correct amplitude.
- There is a phase error which is reduced by reducing the time step.
- The total phase error grows with time.

y phase error we mean that the peaks of the numerical solution have incorrect ositions compared with the peaks of the exact cosine solution. This effect an be understood as if also the numerical solution is on the form  $I\cos\tilde{\omega}t$ , but here  $\tilde{\omega}$  is not exactly equal to  $\omega$ . Later, we shall mathematically quantify this umerical frequency  $\tilde{\omega}$ .

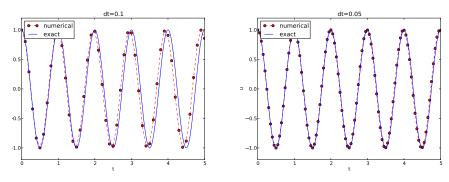

Figure 1: Effect of halving the time step.

#### 3.1 Using a moving plot window

In vibration problems it is often of interest to investigate the system's leaver long time intervals. Errors in the phase may then show up as crucial investigate long time series by introducing a moving plot window that calong with the p most recently computed periods of the solution. The Spackage contains a convenient tool for this: MovingPlotWindow. Typing scitools.MovingPlotWindow shows a demo and description of usage function below illustrates the usage and is invoked in the vib\_undamped. if the number of periods in the simulation exceeds 10:

```
def visualize_front(u, t, I, w, savefig=False):
    Visualize u and the exact solution vs t, using a
    moving plot window and continuous drawing of the
    curves as they evolve in time.
    Makes it easy to plot very long time series.
    import scitools.std as st
    from scitools.MovingPlotWindow import MovingPlotWindow
    P = 2*pi/w # one period
    umin = 1.2*u.min(); umax = -umin
    plot manager = MovingPlotWindow(
        window width=8*P,
        dt=t[1]-t[0],
        yaxis=[umin, umax],
        mode='continuous drawing')
    for n in range(1,len(u)):
        if plot_manager.plot(n):
            s = plot_manager.first_index_in_plot
            st.plot(t[s:n+1], u[s:n+1], 'r-1',
                    t[s:n+1], I*cos(w*t)[s:n+1], 'b-1',
                    title='t=%6.3f' % t[n],
                    axis=plot_manager.axis(),
                    show=not savefig) # drop window if savefig
            if savefig:
                filename = 'tmp_vib%04d.png' % n
                st.savefig(filename)
                print 'making plot file', filename, 'at t=\%g' \% t
        plot manager.update(n)
```

Running

Terminal> python vib\_undamped.py --dt 0.05 --num\_periods 40

makes the simulation last for 40 periods of the cosine function. With the plot window we can follow the numerical and exact solution as time properties and we see from this demo that the phase error is small in the beginning, becomes more prominent with time. Running vib\_undamped.py with a clearly shows that the phase errors become significant even earlier in the series and destroys the solution.

<sup>3</sup>http://code.google.com/p/scitools

#### .2 Making a video

he visualize\_front function stores all the plots in files whose names are umbered: tmp\_vib0000.png, tmp\_vib0001.png, tmp\_vib0002.png, and so on. rom these files we may make a movie. The Flash format is popular,

```
erminal> avconv -r 12 -i tmp_vib%04d.png -c:v flv movie.flv
```

he avconv program can be replaced by the ffmpeg program in the above mmand if desired. The -r option should come first and describes the number f frames per second in the movie. The -i option describes the name of the plot les. Other formats can be generated by changing the video codec and equipping ne video file with the right extension:

Format	Codec and filename				
Flash	-c:v flv movie.flv				
MP4	-c:v libx264 movie.mp4				
Webm	-c:v libvpx movie.webm				
Ogg	-c:v libtheora movie.ogg				

he video file can be played by some video player like vlc, mplayer, gxine, or otem, e.g.,

```
erminal> vlc movie.webm
```

web page can also be used to play the movie. Today's standard is to use the TML5 video tag:

#### Caution: number the plot files correctly.

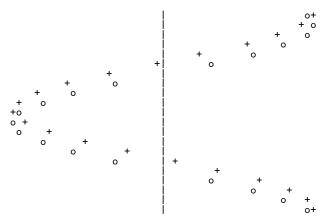

To ensure that the individual plot frames are shown in correct order, it is important to number the files with zero-padded numbers (0000, 0001, 0002, etc.). The printf format %04d specifies an integer in a field of width 4, padded with zeros from the left. A simple Unix wildcard file specification like tmp\_vib\*.png will then list the frames in the right order. If the numbers in the filenames were not zero-padded, the frame tmp\_vib11.png would appear before tmp\_vib2.png in the movie.

#### 3.3 Using a line-by-line ascii plotter

Plotting functions vertically, line by line, in the terminal window using as acters only is a simple, fast, and convenient visualization technique for lc series (the time arrow points downward). The tool scitools.avplotter. makes it easy to create such plots:

```
def visualize_front_ascii(u, t, I, w, fps=10):
    Plot u and the exact solution vs t line by line in a
    terminal window (only using ascii characters).
    Makes it easy to plot very long time series.
    from scitools.avplotter import Plotter
    import time
    P = 2*pi/w
    umin = 1.2*u.min(); umax = -umin
    p = Plotter(ymin=umin, ymax=umax, width=60, symbols='+o')
    for n in range(len(u)):
        print p.plot(t[n], u[n], I*cos(w*t[n])), \
              ,, 1f, % (t[n]/b)
        time.sleep(1/float(fps))
if __name__ == '__main__':
    main()
    raw_input()
```

The call p.plot returns a line of text, with the t axis marked and a symble first function (u) and o for the second function (the exact solution). append this text a time counter reflecting how many periods the curre point corresponds to. A typical output ( $\omega = 2\pi$ ,  $\Delta t = 0.05$ ) looks like t

#### 3.4 Empirical analysis of the solution

For oscillating functions like those in Figure 1 we may compute the an and frequency (or period) empirically. That is, we run through the

plution points  $(t_n, u_n)$  and find all maxima and minima points. The distance etween two consecutive maxima (or minima) points can be used as estimate of ne local period, while half the difference between the u value at a maximum and a nearby minimum gives an estimate of the local amplitude.

The local maxima are the points where

$$u^{n-1} < u^n > u^{n+1}, \quad n = 1, \dots, N_t - 1,$$
 (13)

nd the local minima are recognized by

$$u^{n-1} > u^n < u^{n+1}, \quad n = 1, \dots, N_t - 1.$$
 (14)

1 computer code this becomes

```
lef minmax(t, u):
    minima = []; maxima = []
    for n in range(1, len(u)-1, 1):
        if u[n-1] > u[n] < u[n+1]:
            minima.append((t[n], u[n]))
        if u[n-1] < u[n] > u[n+1]:
            maxima.append((t[n], u[n]))
    return minima, maxima
```

ote that the returned objects are list of tuples.

Let  $(t_i, e_i)$ , i = 0, ..., M - 1, be the sequence of all the M maxima points, here  $t_i$  is the time value and  $e_i$  the corresponding u value. The local period an be defined as  $p_i = t_{i+1} - t_i$ . With Python syntax this reads

```
lef periods(maxima):
    p = [extrema[n][0] - maxima[n-1][0]
        for n in range(1, len(maxima))]
    return np.array(p)
```

he list p created by a list comprehension is converted to an array since we robably want to compute with it, e.g., find the corresponding frequencies \*pi/p.

Having the minima and the maxima, the local amplitude can be calculated s the difference between two neighboring minimum and maximum points:

```
lef amplitudes(minima, maxima):
    a = [(abs(maxima[n][1] - minima[n][1]))/2.0
        for n in range(min(len(minima),len(maxima)))]
    return np.array(a)
```

he code segments are found in the file vib\_empirical\_analysis.py4.

Visualization of the periods p or the amplitudes a it is most conveniently one with just a counter on the horizontal axis, since a[i] and p[i] correspond the i-th amplitude estimate and the i-th period estimate, respectively. There no unique time point associated with either of these estimate since values at wo different time points were used in the computations.

In the analysis of very long time series, it is advantageous to compute and plot and a instead of u to get an impression of the development of the oscillations.

#### 4 Analysis of the numerical scheme

#### 4.1 Deriving a solution of the numerical scheme

After having seen the phase error grow with time in the previous sect shall now quantify this error through mathematical analysis. The key the analysis will be to establish an exact solution of the discrete eq The difference equation (7) has constant coefficients and is homogeneo solution is then  $u^n = CA^n$ , where A is some number to be determined f differential equation and C is determined from the initial condition (Recall that n in  $u^n$  is a superscript labeling the time level, while n in exponent. With oscillating functions as solutions, the algebra will be consimplified if we seek an A on the form

$$A = e^{i\tilde{\omega}\Delta t}.$$

and solve for the numerical frequency  $\tilde{\omega}$  rather than A. Note that  $i=\sqrt{-}$  imaginary unit. (Using a complex exponential function gives simpler arit than working with a sine or cosine function.) We have

$$A^{n} = e^{i\tilde{\omega}\Delta t \, n} = e^{i\tilde{\omega}t} = \cos(\tilde{\omega}t) + i\sin(\tilde{\omega}t) \, .$$

The physically relevant numerical solution can be taken as the real parcomplex expression.

The calculations goes as

$$[D_t D_t u]^n = \frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2}$$

$$= I \frac{A^{n+1} - 2A^n + A^{n-1}}{\Delta t^2}$$

$$= I \frac{\exp(i\tilde{\omega}(t + \Delta t)) - 2\exp(i\tilde{\omega}t) + \exp(i\tilde{\omega}(t - \Delta t))}{\Delta t^2}$$

$$= I \exp(i\tilde{\omega}t) \frac{1}{\Delta t^2} (\exp(i\tilde{\omega}(\Delta t)) + \exp(i\tilde{\omega}(-\Delta t)) - 2)$$

$$= I \exp(i\tilde{\omega}t) \frac{2}{\Delta t^2} (\cosh(i\tilde{\omega}\Delta t) - 1)$$

$$= I \exp(i\tilde{\omega}t) \frac{2}{\Delta t^2} (\cos(\tilde{\omega}\Delta t) - 1)$$

$$= -I \exp(i\tilde{\omega}t) \frac{4}{\Delta t^2} \sin^2(\frac{\tilde{\omega}\Delta t}{2})$$

The last line follows from the relation  $\cos x - 1 = -2\sin^2(x/2)$  (try coin wolframalpha.com<sup>5</sup> to see the formula).

The scheme (7) with  $u^n = Ie^{i\omega\tilde{\Delta}t\,n}$  inserted now gives

<sup>4</sup>http://tinyurl.com/nm5587k/vib/vib empirical analysis.py

<sup>&</sup>lt;sup>5</sup>http://www.wolframalpha.com

$$-Ie^{i\tilde{\omega}t}\frac{4}{\Delta t^2}\sin^2(\frac{\tilde{\omega}\Delta t}{2}) + \omega^2 Ie^{i\tilde{\omega}t} = 0, \tag{15}$$

hich after dividing by  $Ie^{i\tilde{\omega}t}$  results in

$$\frac{4}{\Delta t^2} \sin^2(\frac{\tilde{\omega}\Delta t}{2}) = \omega^2. \tag{16}$$

he first step in solving for the unknown  $\tilde{\omega}$  is

$$\sin^2(\frac{\tilde{\omega}\Delta t}{2}) = \left(\frac{\omega\Delta t}{2}\right)^2.$$

hen, taking the square root, applying the inverse sine function, and multiplying y  $2/\Delta t$ , results in

$$\tilde{\omega} = \pm \frac{2}{\Delta t} \sin^{-1} \left( \frac{\omega \Delta t}{2} \right) \,. \tag{17}$$

The first observation of (17) tells that there is a phase error since the umerical frequency  $\tilde{\omega}$  never equals the exact frequency  $\omega$ . But how good is ne approximation (17)? That is, what is the error  $\omega - \tilde{\omega}$  or  $\tilde{\omega}/\omega$ ? Taylor series chansion for small  $\Delta t$  may give an expression that is easier to understand than ne complicated function in (17):

```
>>> from sympy import *
>>> dt, w = symbols('dt w')
>>> w_tilde_e = 2/dt*asin(w*dt/2)
>>> w_tilde_series = w_tilde_e.series(dt, 0, 4)
>>> print w_tilde_series
v + dt**2*w**3/24 + 0(dt**4)
```

his means that

$$\tilde{\omega} = \omega \left( 1 + \frac{1}{24} \omega^2 \Delta t^2 \right) + \mathcal{O}(\Delta t^4) \,. \tag{18}$$

he error in the numerical frequency is of second-order in  $\Delta t$ , and the error anishes as  $\Delta t \to 0$ . We see that  $\tilde{\omega} > \omega$  since the term  $\omega^3 \Delta t^2/24 > 0$  and this by far the biggest term in the series expansion for small  $\omega \Delta t$ . A numerical equency that is too large gives an oscillating curve that oscillates too fast and erefore "lags behind" the exact oscillations, a feature that can be seen in the lots.

Figure 2 plots the discrete frequency (17) and its approximation (18) for = 1 (based on the program vib\_plot\_freq.py<sup>6</sup>). Although  $\tilde{\omega}$  is a function  $\Delta t$  in (18), it is misleading to think of  $\Delta t$  as the important discretization arameter. It is the product  $\omega \Delta t$  that is the key discretization parameter. This uantity reflects the number of time steps per period of the oscillations. To see his, we set  $P = N_P \Delta t$ , where P is the length of a period, and  $N_P$  is the number

of time steps during a period. Since P and  $\omega$  are related by  $P = 2\pi/\omega$  that  $\omega \Delta t = 2\pi/N_P$ , which shows that  $\omega \Delta t$  is directly related to  $N_P$ .

The plot shows that at least  $N_P \sim 25-30$  points per period are not for reasonable accuracy, but this depends on the length of the simulation the total phase error due to the frequency error grows linearly with ti Exercise 2).

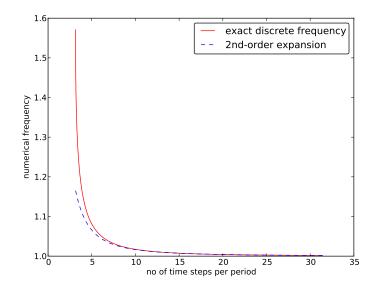

Figure 2: Exact discrete frequency and its second-order series expan

#### 4.2 Exact discrete solution

Perhaps more important than the  $\tilde{\omega} = \omega + \mathcal{O}(\Delta t^2)$  result found above is that we have an exact discrete solution of the problem:

$$u^n = I\cos(\tilde{\omega}n\Delta t), \quad \tilde{\omega} = \frac{2}{\Delta t}\sin^{-1}\left(\frac{\omega\Delta t}{2}\right).$$

We can then compute the error mesh function

$$e^n = u_e(t_n) - u^n = I\cos(\omega n\Delta t) - I\cos(\tilde{\omega} n\Delta t)$$
.

In particular, we can use this expression to show *convergence* of the nu scheme, i.e.,  $e^n \to 0$  as  $\Delta t \to 0$ . We have that

$$\lim_{\Delta t \to 0} \tilde{\omega} = \lim_{\Delta t \to 0} \frac{2}{\Delta t} \sin^{-1} \left( \frac{\omega \Delta t}{2} \right) = \omega,$$

<sup>6</sup>http://tinyurl.com/nm5587k/vib/vib\_plot\_freq.py

y L'Hopital's rule or simply asking (2/x)\*asin(w\*x/2) as x->0 in Wolfra-Alpha<sup>7</sup>. Therefore,  $\tilde{\omega} \to \omega$ , and the two terms in  $e^n$  cancel each other in the mit  $\Delta t \to 0$ .

The error mesh function is ideal for verification purposes and you are strongly accouraged to make a test based on (19) by doing Exercise 10.

#### .3 The global error

o achieve more analytical insight into the nature of the global error, we can aylor expand the error mesh function. Since  $\tilde{\omega}$  contains  $\Delta t$  in the denominator e use the series expansion for  $\tilde{\omega}$  inside the cosine function:

```
>>> dt, w, t = symbols('dt w t')
>>> w_tilde_e = 2/dt*asin(w*dt/2)
>>> w_tilde_series = w_tilde_e.series(dt, 0, 4)
>>> # Get rid of O() term
>>> w_tilde_series = sum(w_tilde_series.as_ordered_terms()[:-1])
>>> w_tilde_series
lt**2*w**3/24 + w
>>> error = cos(w*t) - cos(w_tilde_series*t)
>>> error.series(dt, 0, 6)
lt**2*t*w**3*sin(t*w)/24 + dt**4*t**2*w**6*cos(t*w)/1152 + O(dt**6)
>>> error.series(dt, 0, 6).as_leading_term(dt)
lt**2*t*w**3*sin(t*w)/24
```

his means that the leading order global (true) error at a point t is proportional  $\omega^3 t \Delta t^2$ . Setting  $t = n \Delta t$  and replacing  $\sin(\omega t)$  by its maximum value 1, we ave the analytical leading-order expression

$$e^n = \frac{1}{24}n\omega^3 \Delta t^3,$$

nd the  $\ell^2$  norm of this error can be computed as

$$||e^n||_{\ell^2}^2 = \Delta t \sum_{n=0}^{N_t} \frac{1}{24^2} n^2 \omega^6 \Delta t^6 = \frac{1}{24^2} \omega^6 \Delta t^7 \sum_{n=0}^{N_t} n^2.$$

he sum  $\sum_{n=0}^{N_t} n^2$  is approximately equal to  $\frac{1}{3}N_t^3$ . Replacing  $N_t$  by  $T/\Delta t$  and aking the square root gives the expression

$$||e^n||_{\ell^2} = \frac{1}{24} \sqrt{\frac{T^3}{3}} \omega^3 \Delta t^2,$$

hich shows that also the integrated error is proportional to  $\Delta t^2$ .

#### .4 Stability

ooking at (19), it appears that the numerical solution has constant and correct mplitude, but an error in the frequency (phase error). However, there is another

error that is more serious, namely an unstable growing amplitude that  $\operatorname{c} \iota$  of  $\Delta t$  is too large.

We realize that a constant amplitude demands  $\tilde{\omega}$  to be a real nun complex  $\tilde{\omega}$  is indeed possible if the argument x of  $\sin^{-1}(x)$  has magnitude than unity: |x| > 1 (type  $\mathtt{asin}(\mathtt{x})$  in wolframalpha.com<sup>8</sup> to see basic prop  $\sin^{-1}(x)$ ). A complex  $\tilde{\omega}$  can be written  $\tilde{\omega} = \tilde{\omega}_r + i\tilde{\omega}_i$ . Since  $\sin^{-1}(x)$  has a imaginary part for x > 1,  $\tilde{\omega}_i < 0$ , it means that  $\exp(i\omega \tilde{t}) = \exp(-\tilde{\omega}_i t)$  exwill lead to exponential growth in time because  $\exp(-\tilde{\omega}_i t)$  with  $\tilde{\omega}_i < \mathrm{positive}$  exponent.

We do not tolerate growth in the amplitude and we therefore have a criterion arising from requiring the argument  $\omega \Delta t/2$  in the inverse sine to be less than one:

$$\frac{\omega \Delta t}{2} \le 1 \quad \Rightarrow \quad \Delta t \le \frac{2}{\omega}$$
.

With  $\omega=2\pi$ ,  $\Delta t>\pi^{-1}=0.3183098861837907$  will give growing so Figure 3 displays what happens when  $\Delta t=0.3184$ , which is slightly at critical value:  $\Delta t=\pi^{-1}+9.01\cdot 10^{-5}$ .

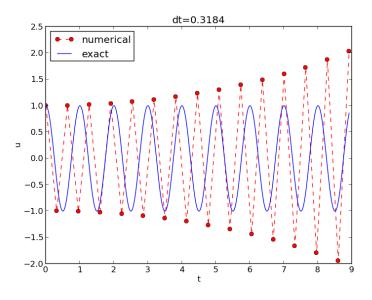

Figure 3: Growing, unstable solution because of a time step slightly the stability limit.

<sup>&</sup>lt;sup>7</sup>http://www.wolframalpha.com/input/?i=%282%2Fx%29\*asin%28w\*x%2F2%29+as+x-%3E0

<sup>8</sup>http://www.wolframalpha.com

#### .5 About the accuracy at the stability limit

n interesting question is whether the stability condition  $\Delta t < 2/\omega$  is unfortunate, r more precisely: would it be meaningful to take larger time steps to speed p computations? The answer is a clear no. At the stability limit, we have not  $\sin^{-1}\omega\Delta t/2 = \sin^{-1}1 = \pi/2$ , and therefore  $\tilde{\omega} = \pi/\Delta t$ . (Note that the pproximate formula (18) is very inaccurate for this value of  $\Delta t$  as it predicts = 2.34/pi, which is a 25 percent reduction.) The corresponding period of the umerical solution is  $\tilde{P} = 2\pi/\tilde{\omega} = 2\Delta t$ , which means that there is just one time sep  $\Delta t$  between a peak and a through in the numerical solution. This is the nortest possible wave that can be represented in the mesh. In other words, it is of meaningful to use a larger time step than the stability limit.

Also, the phase error when  $\Delta t=2/\omega$  is severe: Figure 4 shows a comparison f the numerical and analytical solution with  $\omega=2\pi$  and  $\Delta t=2/\omega=\pi^{-1}$ . lready after one period, the numerical solution has a through while the exact plution has a peak (!). The error in frequency when  $\Delta t$  is at the stability limit ecomes  $\omega-\tilde{\omega}=\omega(1-\pi/2)\approx-0.57\omega$ . The corresponding error in the period  $P-\tilde{P}\approx0.36P$ . The error after m periods is then 0.36mP. This error has each half a period when  $m=1/(2\cdot0.36)\approx1.38$ , which theoretically confirms the observations in Figure 4 that the numerical solution is a through ahead of a eak already after one and a half period.

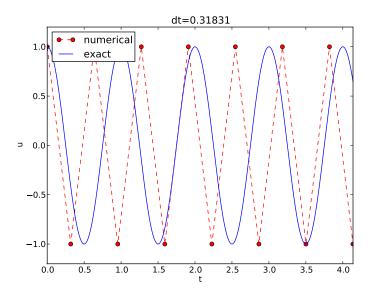

Figure 4: Numerical solution with  $\Delta t$  exactly at the stability limit.

#### Summary.

From the accuracy and stability analysis we can draw three impo conclusions:

- 1. The key parameter in the formulas is  $p = \omega \Delta t$ . The period oscillations is  $P = 2\pi/\omega$ , and the number of time steps per period  $N_P = P/\Delta t$ . Therefore,  $p = \omega \Delta t = 2\pi N_P$ , showing that the craparameter is the number of time steps per period. The small possible  $N_P$  is 2, showing that  $p \in (0, \pi]$ .
- 2. Provided  $p \leq 2$ , the amplitude of the numerical solution is cons
- 3. The numerical solution exhibits a relative phase error  $\tilde{\omega}/\omega \approx \frac{1}{24}p^2$ . This error leads to wrongly displaced peaks of the numerical solution, and the error in peak location grows linearly with time Exercise 2).

# 5 Alternative schemes based on 1st-order ctions

A standard technique for solving second-order ODEs is to rewrite the system of first-order ODEs and then apply the vast collection of meth first-order ODE systems. Given the second-order ODE problem

$$u'' + \omega^2 u = 0$$
,  $u(0) = I$ ,  $u'(0) = 0$ ,

we introduce the auxiliary variable v = u' and express the ODE proterms of first-order derivatives of u and v:

$$u' = v,$$
  
$$v' = -\omega^2 u.$$

The initial conditions become u(0) = I and v(0) = 0.

#### 6 Standard methods for 1st-order ODE sys

#### 6.1 The Forward Euler scheme

A Forward Euler approximation to our  $2 \times 2$  system of ODEs (22)-(23) l

$$[D_t^+ u = v]^n, [D_t^+ v = -\omega^2 u]^n,$$

r written out,

$$u^{n+1} = u^n + \Delta t v^n, \tag{25}$$

$$v^{n+1} = v^n - \Delta t \omega^2 u^n \,. \tag{26}$$

Let us briefly compare this Forward Euler method with the centered difference theme for the second-order differential equation. We have from (25) and (26) pplied at levels n and n-1 that

$$u^{n+1} = u^n + \Delta t v^n = u^n + \Delta t (v^{n-1} - \Delta t \omega^2 u^{n-1}).$$

ince from (25)

$$v^{n-1} = \frac{1}{\Delta t} (u^n - u^{n-1}),$$

follows that

$$u^{n+1} = 2u^n - u^{n-1} - \Delta t^2 \omega^2 u^{n-1}.$$

hich is very close to the centered difference scheme, but the last term is evaluated t $t_{n-1}$  instead of  $t_n$ . Dividing by  $\Delta t^2$ , the left-hand side is an approximation of u'' at  $t_n$ , while the right-hand side is sampled at  $t_{n-1}$ . This inconsistency in the scheme turns out to be rather crucial for the accuracy of the Forward Euler lethod applied to vibration problems.

#### .2 The Backward Euler scheme

Backward Euler approximation the ODE system is equally easy to write up in 12 operator notation:

$$[D_t^- u = v]^{n+1}, (27)$$

$$[D_t^- v = -\omega u]^{n+1}. (28)$$

his becomes a coupled system for  $u^{n+1}$  and  $v^{n+1}$ :

$$u^{n+1} - \Delta t v^{n+1} = u^n, (29)$$

$$v^{n+1} + \Delta t \omega^2 u^{n+1} = v^n. (30)$$

We can compare (29)-(30) with central the scheme for the second-order ifferential equation. To this end, we eliminate  $v^{n+1}$  in (29) using (30) solved ith respect to  $v^{n+1}$ . Thereafter, we eliminate  $v^n$  using (29) solved with respect  $v^{n+1}$  and replacing n+1 by n. The resulting equation involving only  $u^{n+1}$ , n, and  $u^{n-1}$  can be ordered as

$$\frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2} = -\omega^2 u^{n+1},$$

which has almost the same form as the centered scheme for the secon differential equation, but the right-hand side is evaluated at  $u^{n+1}$  and This obvious inconsistency has a dramatic effect on the numerical solut

#### 6.3 The Crank-Nicolson scheme

The Crank-Nicolson scheme takes this form in the operator notation:

$$[D_t u = \overline{v}^t]^{n + \frac{1}{2}},$$
  

$$[D_t v = -\omega \overline{u}^t]^{n + \frac{1}{2}}.$$

Writing the equations out shows that this is also a coupled system:

$$u^{n+1} - \frac{1}{2}\Delta t v^{n+1} = u^n + \frac{1}{2}\Delta t v^n,$$
  
$$v^{n+1} + \frac{1}{2}\Delta t \omega^2 u^{n+1} = v^n - \frac{1}{2}\Delta t \omega^2 u^n.$$

#### 6.4 Comparison of schemes

We can easily compare methods like the ones above (and many more!)  $\tau$  aid of the Odespy<sup>9</sup> package. Below is a sketch of the code.

```
import odespy
import numpy as np
def f(u, t, w=1):
    u, v = u # u is array of length 2 holding our [u, v]
def run solvers and plot(solvers, timesteps per period=20,
                         num_periods=1, I=1, w=2*np.pi):
    P = 2*np.pi/w # duration of one period
    dt = P/timesteps_per_period
    Nt = num_periods*timesteps_per_period
    T = Nt*dt
    t_mesh = np.linspace(0, T, Nt+1)
    legends = []
    for solver in solvers:
        solver.set(f_kwargs={'w': w})
        solver.set_initial_condition([I, 0])
        u. t = solver.solve(t mesh)
```

There is quite some more code dealing with plots also, and we refer to the file vib\_undamped\_odespy.py<sup>10</sup> for details. Observe that keyword argur f(u,t,w=1) can be supplied through a solver parameter f\_kwargs (dietails) of additional keyword arguments to f).

<sup>9</sup>https://github.com/hplgit/odespy

<sup>10</sup>http://tinyurl.com/nm5587k/vib/vib\_undamped\_odespy.py

Specification of the Forward Euler, Backward Euler, and Crank-Nicolson chemes is done like this:

```
solvers = [
   odespy.ForwardEuler(f),
   # Implicit methods must use Newton solver to converge
   odespy.BackwardEuler(f, nonlinear_solver='Newton'),
   odespy.CrankNicolson(f, nonlinear_solver='Newton'),
   ]
```

The vib\_undamped\_odespy.py program makes two plots of the computed plutions with the various methods in the solvers list: one plot with u(t) versus and one phase plane plot where v is plotted against u. That is, the phase lane plot is the curve (u(t),v(t)) parameterized by t. Analytically,  $u=I\cos(\omega t)$  and  $v=u'=-\omega I\sin(\omega t)$ . The exact curve (u(t),v(t)) is therefore an ellipse, hich often looks like a circle in a plot if the axes are automatically scaled. The important feature, however, is that exact curve (u(t),v(t)) is closed and speats itself for every period. Not all numerical schemes are capable to do that, reaning that the amplitude instead shrinks or grows with time.

The Forward Euler scheme in Figure 5 has a pronounced spiral curve, pointing the fact that the amplitude steadily grows, which is also evident in Figure 6. he Backward Euler scheme has a similar feature, except that the spriral goes ward and the amplitude is significantly damped. The changing amplitude nd the sprial form decreases with decreasing time step. The Crank-Nicolson theme looks much more accurate. In fact, these plots tell that the Forward and ackward Euler schemes are not suitable for solving our ODEs with oscillating plutions.

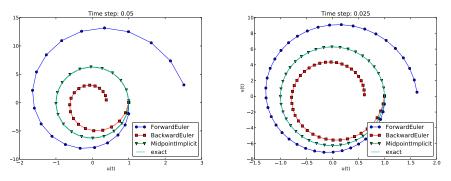

Figure 5: Comparison of classical schemes in the phase plane.

#### .5 Runge-Kutta methods

/e may run two popular standard methods for first-order ODEs, the 2nd- and th-order Runge-Kutta methods, to see how they perform. Figures 7 and 8 show is solutions with larger  $\Delta t$  values than what was used in the previous two plots.

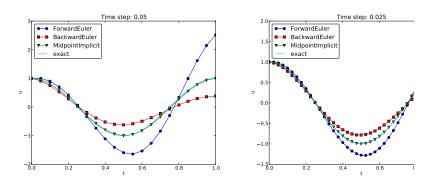

Figure 6: Comparison of classical schemes.

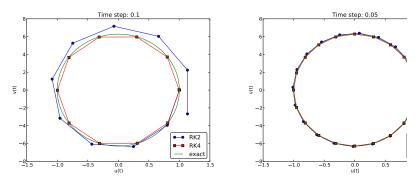

Figure 7: Comparison of Runge-Kutta schemes in the phase plan

The visual impression is that the 4th-order Runge-Kutta method accurate, under all circumstances in these tests, and the 2nd-order schen from amplitude errors unless the time step is very small.

The corresponding results for the Crank-Nicolson scheme are sl Figures 9 and 10. It is clear that the Crank-Nicolson scheme outp the 2nd-order Runge-Kutta method. Both schemes have the same  $\alpha$  accuracy  $\mathcal{O}(\Delta t^2)$ , but their differences in the accuracy that matters is physical application is very clearly pronounced in this example. Exe invites you to investigate how

#### 6.6 Analysis of the Forward Euler scheme

We may try to find exact solutions of the discrete equations in the Forwar method. An "ansatz" is

$$u^n = IA^n,$$
$$v^n = qIA^n.$$

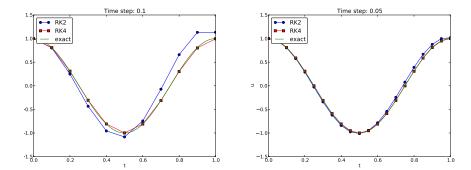

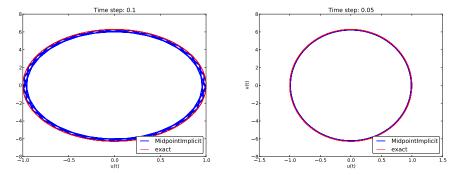

Figure 8: Comparison of Runge-Kutta schemes.

igure 9: Long-time behavior of the Crank-Nicolson scheme in the phase plane.

here q and A are unknown numbers. We could have used a complex exponential orm  $\exp{(i\tilde{\omega}n\Delta t)}$  since we get oscillatory form, but the oscillations grow in the orward Euler method, so the numerical frequency  $\tilde{\omega}$  will be complex anyway o produce an exponentially growing amplitude), so it is easier to just work ith potentially complex A and q as introduced above.

The Forward Euler scheme leads to

$$A = 1 + \Delta t q,$$
  

$$A = 1 - \Delta t \omega^2 q^{-1}.$$

/e can easily eliminate A, get  $q^2 + \omega^2 = 0$ , and solve for

$$q = \pm i\omega$$
,

hich gives

$$A = 1 \pm \Delta t i \omega$$
.

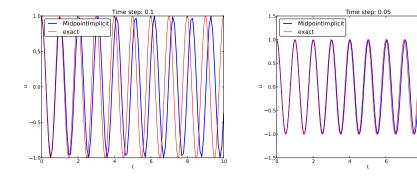

Figure 10: Long-time behavior of the Crank-Nicolson scheme.

We shall take the real part of  $A^n$  as the solution. The two values complex conjugates, and the real part of  $A^n$  will be the same for the tw This is easy to realize if we rewrite the complex numbers in polar form which is also convenient for further analysis and understanding. The pol of the two values for A become

$$1 \pm \Delta t i \omega = \sqrt{1 + \omega^2 \Delta t^2} e^{\pm i \tan^{-1}(\omega \Delta t)}.$$

Now.

$$(1 \pm \Delta t i\omega)^n = (1 + \omega^2 \Delta t^2) n / 2e^{\pm ni \tan^{-1}(\omega \Delta t)}.$$

Since  $\cos(\theta n) = \cos(-\theta n)$ , the real part of the two numbers become the We therefore continue with the solution that has the plus sign.

The general solution is  $u^n = CA^n$ , where C is a constant. This is det from the initial condition:  $u^0 = C = I$ . Then also  $v^n = qIA^n$ . T solutions consist of the real part of the expressions in polar form:

$$u^{n} = I(1+\omega^{2}\Delta t^{2})n/2\cos(n\tan^{-1}(\omega\Delta t)), \quad v^{n} = -\omega I(1+\omega^{2}\Delta t^{2})n/2\sin^{-1}(\omega\Delta t)$$

The expression  $(1 + \omega^2 \Delta t^2)n/2$  causes growth of the amplitude, since a greater than one is raised to an integer power. By expanding first the root,  $\sqrt{1+x^2} \approx 1 + \frac{1}{2}x^2$ , we realize that raising the approximation to any power, will give rise to a polynomial with leading terms  $1 + x^2$ , or with as in our case, the amplitude in the Forward Euler scheme grows as  $1 + \frac{1}{2}x^2 + \frac{$ 

#### 7 Energy considerations

The observations of various methods in the previous section can be interpreted if we compute an quantity reflecting the total *energy of the* It turns out that this quantity,

$$E(t) = \frac{1}{2}(u')^2 + \frac{1}{2}\omega^2 u^2,$$

constant for all t. Checking that E(t) really remains constant brings evidence nat the numerical computations are sound. Such energy measures, when they xist, are much used to check numerical simulations.

#### .1 Derivation of the energy expression

le starting multiplying

$$u'' + \omega^2 u = 0,$$

y u' and integrating from 0 to T:

$$\int_0^T u''u'dt + \int_0^T \omega^2 uu'dt = 0.$$

bserving that

$$u''u' = \frac{d}{dt}\frac{1}{2}(u')^2$$
,  $uu' = \frac{d}{dt}\frac{1}{2}u^2$ ,

e get

$$\int_0^T \left(\frac{d}{dt}\frac{1}{2}(u')^2 + \frac{d}{dt}\frac{1}{2}\omega^2 u^2\right)dt = E(T) - E(0) = 0,$$

here we have introduced the energy measure E(t)

$$E(t) = \frac{1}{2}(u')^2 + \frac{1}{2}\omega^2 u^2.$$
 (35)

he important result from this derivation is that the total energy is constant:

$$E(t) = E(0).$$

#### Warning.

The quantity E(t) derived above is physically not the energy of a vibrating mechanical system, but the energy per unit mass. To see this, we start with Newton's second law F = ma (F is the sum of forces, m is the mass of the system, and a is the acceleration). The displacement u is related to a through a = u''. With a spring force as the only force we have F = -ku, where k is a spring constant measuring the stiffness of the spring. Newton's second law then implies the differential equation

$$-ku = mu'' \implies mu'' + ku = 0.$$

This equation of motion can be turned into an energy balance equation finding the work done by each term during a time interval [0, T]. To end, we multiply the equation by du = u'dt and integrate:

$$\int_0^T muu'dt + \int_0^T kuu'dt = 0.$$

The result is

$$E(t) = E_k(t) + E_p(t) = 0,$$

where

$$E_k(t) = \frac{1}{2}mv^2, \quad v = u',$$

is the *kinetic energy* of the system,

$$E_p(t) = \frac{1}{2}ku^2$$

is the potential energy, and the sum E(t) is the total energy. The deriv demonstrates the famous energy principle that any change in the ki energy is due to a change in potential energy and vice versa.

The equation mu'' + ku = 0 can be divided by m and writte  $u'' + \omega^2 u = 0$  for  $\omega = \sqrt{k/m}$ . The energy expression  $E(t) = \frac{1}{2}(u')^2 + \frac{1}{2}$  derived earlier is then simply the true physical total energy  $\frac{1}{2}m(u')^2 + \frac{1}{2}$  divided by m, i.e., total energy per unit mass.

**Energy of the exact solution.** Analytically, we have u(t) = I c u(0) = I and u'(0) = 0, so we can easily check that the evolution of the E(t) is constant:

$$E(t) = \frac{1}{2}I^{2}(-\omega\sin\omega t)^{2} + \frac{1}{2}\omega^{2}I^{2}\cos^{2}\omega t = \frac{1}{2}\omega^{2}(\sin^{2}\omega t + \cos^{2}\omega t) =$$

#### 7.2 An error measure based on total energy

The error in total energy, as a mesh function, can be computed by

$$e_E^n = \frac{1}{2} \left( \frac{u^{n+1} - u^{n-1}}{2\Delta t} \right)^2 + \frac{1}{2} \omega^2 (u^n)^2 - E(0), \quad n = 1, \dots, N_t - 1,$$

where

$$E(0) = \frac{1}{2}V^2 + \frac{1}{2}\omega^2 I^2,$$

u(0) = I and u'(0) = V. A useful norm can be the maximum absolute value  $e_E^n$ :

$$||e_E^n||_{\ell^{\infty}} = \max_{1 \le n < N_t} |e_E^n|.$$

he corresponding Python implementation takes the form

The convergence rates of the quantity e\_E\_norm can be used for verification. he value of e\_E\_norm is also useful for comparing schemes through their ability preserve energy. Below is a table demonstrating the error in total energy or various schemes. We clearly see that the Crank-Nicolson and 4th-order unge-Kutta schemes are superior to the 2nd-order Runge-Kutta method and ven more superior to the Forward and Backward Euler schemes.

Method	T	$\Delta t$	$\max  e_E^n $
Forward Euler	1	0.05	$1.113 \cdot 10^2$
Forward Euler	1	0.025	$3.312 \cdot 10^{1}$
Backward Euler	1	0.05	$1.683 \cdot 10^{1}$
Backward Euler	1	0.025	$1.231 \cdot 10^{1}$
Runge-Kutta 2nd-order	1	0.1	8.401
Runge-Kutta 2nd-order	1	0.05	$9.637 \cdot 10^{-1}$
Crank-Nicolson	1	0.05	$9.389 \cdot 10^{-1}$
Crank-Nicolson	1	0.025	$2.411 \cdot 10^{-1}$
Runge-Kutta 4th-order	1	0.1	2.387
Runge-Kutta 4th-order	1	0.05	$6.476 \cdot 10^{-1}$
Crank-Nicolson	10	0.1	3.389
Crank-Nicolson	10	0.05	$9.389 \cdot 10^{-1}$
Runge-Kutta 4th-order	10	0.1	3.686
Runge-Kutta 4th-order	10	0.05	$6.928 \cdot 10^{-1}$

#### The Euler-Cromer method

/hile the 4th-order Runge-Kutta method and the a centered Crank-Nicolson sheme work well for the first-order formulation of the vibration model, both were iferior to the straightforward centered difference scheme for the second-order quation  $u'' + \omega^2 u = 0$ . However, there is a similarly successful scheme available or the first-order system u' = v,  $v' = -\omega^2 u$ , to be presented next.

#### 8.1 Forward-backward discretization

The idea is to apply a Forward Euler discretization to the first equatio Backward Euler discretization to the second. In operator notation this i as

$$[D_t^+ u = v]^n,$$
  

$$[D_t^- v = -\omega u]^{n+1}.$$

We can write out the formulas and collect the unknowns on the left-han

$$u^{n+1} = u^n + \Delta t v^n,$$
  
$$v^{n+1} = v^n - \Delta t \omega^2 u^{n+1}.$$

We realize that  $u^{n+1}$  can be computed from (41) and then  $v^{n+1}$  from (4 the recently computed value  $u^{n+1}$  on the right-hand side.

In physics, it is more common to update the v equation first, with a difference, and thereafter the u equation, with a backward difference that the most recently computed v value:

$$v^{n+1} = v^n - \Delta t \omega^2 u^n,$$
  
$$u^{n+1} = u^n + \Delta t v^{n+1}.$$

The advantage of this sequence of the first-order ODEs becomes evident we turn to more complicated models. A typical vibration ODE can in be written as

$$\ddot{u} + g(u, u', t) = 0,$$

which results in the system

$$v' = -g(u, v, t),$$
  
$$u' = v,$$

and the scheme

$$v^{n+1} = v^n - \Delta t g(u^n, v^n, t),$$
  
 $u^{n+1} = u^n + \Delta t v^{n+1}.$ 

We realize that the first update works well with any g since old values  $v^n$  are used. Switching the equations would demand  $u^n+1$  and  $v^{n+1}$  val

The scheme (44)-(43) goes under several names: Forward-backward Semi-implicit Euler method<sup>11</sup>, symplectic Euler, semi-explicit Euler, I Störmer-Verlet, and Euler-Cromer. We shall stick to the latter name. Six

<sup>11</sup> http://en.wikipedia.org/wiki/Semi-implicit\_Euler\_method

me discretizations are based on first-order difference approximation, one may nink that the scheme is only of first-order, but this is not true: the use of a rward and then a backward difference make errors cancel so that the overall ror in the scheme is  $\mathcal{O}(\Delta t^2)$ . This is explaned below.

#### .2 Equivalence with the scheme for the second-order ODE

We may eliminate the  $v^n$  variable from (41)-(42) or (44)-(43). The  $v^{n+1}$  term in (3) can be eliminated from (44):

$$u^{n+1} = u^n + \Delta t(v^n - \omega^2 \Delta t^2 u^n). \tag{45}$$

he  $v^n$  quantity can be expressed by  $u^n$  and  $u^{n-1}$  using (44):

$$v^n = \frac{u^n - u^{n-1}}{\Delta t},$$

nd when this is inserted in (45) we get

$$u^{n+1} = 2u^n - u^{n-1} - \Delta t^2 \omega^2 u^n, \tag{46}$$

hich is nothing but the centered scheme (7)! Therefore, the previous analysis f (7) also applies to the Euler-Cromer method. In particular, the amplitude constant, given that the stability criterion is fulfilled, but there is always a hase error (18). Exercise 20 gives guidance on how to derive the exact discrete plution of the two equations in the Euler-Cromer method.

The initial condition u'=0 means u'=v=0. From (44) we get  $v^1=-\omega^2u^0$  nd  $u^1=u^0-\omega^2\Delta t^2u^0$ , which is not exactly the same  $u^1$  value as obtained by centered approximation of v'(0)=0 and combined with the discretization (7) f the second-order ODE: a factor  $\frac{1}{2}$  is missing in the second term. In fact, if e approximate u'(0)=0 by a backward difference,  $(u^0-u^{-1})/\Delta t=0$ , we get  $^{-1}=u^0$ , and when combined with (7), it results in  $u^1=u^0-\omega^2\Delta t^2u^0$ . That , the Euler-Cromer method based on (44)-(43) corresponds to using only a rst-order approximation to the initial condition in the method from Section 1.2.

Correspondingly, using the formulation (41)-(42) with  $v^n=0$  leads to  $u^1=u^0$ , hich can be interpreted as using a forward difference approximation for the itial condition u'(0)=0. Both Euler-Cromer formulations lead to slightly ifferent values for  $u^1$  compared to the method in Section 1.2. The error is  $\omega^2 \Delta t^2 u^0$  and of the same order as the overall scheme.

#### .3 Implementation

he function below, found in  $vib_EulerCromer.py^{12}$  implements the Euler-romer scheme (44)-(43):

from numpy import zeros, linspace

def solver(I, w, dt, T):
 """
 Solve v' = - w\*\*2\*u, u'=v for t in (0,T], u(0)=I and v(0)=0,
 by an Euler-Cromer method.
 """
 dt = float(dt)
 Nt = int(round(T/dt))
 u = zeros(Nt+1)
 v = zeros(Nt+1)
 t = linspace(0, Nt\*dt, Nt+1)

v[0] = 0
 u[0] = I
 for n in range(0, Nt):
 v[n+1] = v[n] - dt\*w\*\*2\*u[n]
 u[n+1] = u[n] + dt\*v[n+1]
 return u, v, t

Since the Euler-Cromer scheme is equivalent to the finite difference for the second-order ODE  $u'' + \omega^2 u = 0$  (see Section 8.2), the performance above solver function is the same as for the solver function in Section only difference is the formula for the first time step, as discussed above deviation in the Euler-Cromer scheme means that the discrete solution is Section 4.2 is not a solution of the Euler-Cromer scheme. To verify the mentation of the Euler-Cromer method we can adjust v[1] so that the configuration of the Euler-Cromer method we can adjust v[1] so that the configuration in an alternative solver function, solver\_ic\_fix in vib\_EulerCromer and combined with a nose test in the function test\_solver that check ity of computed values with the exact discrete solution to machine property and the scheme for the second-oder ODE, arising from the mismatch in time level.

#### 8.4 The velocity Verlet algorithm

Another very popular algorithm for vibration problems  $u'' + \omega^2 u = 0$  derived as follows. First, we step u forward from  $t_n$  to  $t_{n+1}$  using a thr Taylor series,

$$u(t_{n+1}) = u(t_n) + u'(t_n)\Delta t + \frac{1}{2}u''(t_n)\Delta t^2.$$

Using u' = v and  $u'' = -\omega^2 u$ , we get the updating formula

$$u^{n+1} = u^n + v^n \Delta t - \frac{1}{2} \Delta^2 \omega^2 u^n.$$

Second, the first-order equation for v,

$$v' = -\omega^2 u,$$

<sup>12</sup>http://tinyurl.com/nm5587k/vib/vib\_EulerCromer.py

discretized by a centered difference in a Crank-Nicolson fashion at  $t_{n+\frac{1}{2}}$ :

$$\frac{v^{n+1} - v^n}{\Delta t} = -\omega^2 \frac{1}{2} (u^n + u^{n+1}),$$

r in operator form that explicitly demonstrates the thinking:

$$[D_t u = -\omega^2 \bar{u}^t]^{n+\frac{1}{2}}$$
.

o summarize, we have the scheme

$$u^{n+1} = u^n + v^n \Delta t - \frac{1}{2} \Delta^2 \omega^2 u^n \tag{47}$$

$$v^{n+1} = v^n - \frac{1}{2}\Delta t\omega^2(u^n + u^{n+1}), \tag{48}$$

nown as the *velocity Verlet* algorithm. Observe that this scheme is explicit nee  $u^{n+1}$  in (48) is already computed from (47).

The algorithm can be straightforwardly implemented as shown below.

```
from vib undamped import (
   zeros, linspace,
   convergence_rates,
   main)
lef solver(I, w, dt, T, return_v=False):
   Solve u'=v, v'=-w**2*u for t in (0,T], u(0)=I and v(0)=0,
   by the velocity Verlet method with time step dt.
   dt = float(dt)
   Nt = int(round(T/dt))
   u = zeros(Nt+1)
   v = zeros(Nt+1)
   t = linspace(0, Nt*dt, Nt+1)
   v [0] = 0
   for n in range(Nt):
       u[n+1] = u[n] + v[n]*dt - 0.5*dt**2*w**2*u[n]
       v[n+1] = v[n] - 0.5*dt*w**2*(u[n] + u[n+1])
   if return v:
       return u, v, t
       # Return just u and t as in the vib_undamped.py's solver
       return u, t
```

/e provide the option that this solver function returns the same data as the olver function from Section 2.1 (if return\_v is False), but we may return v long with u and t.

The error in the Taylor series expansion behind (47) is  $\mathcal{O}(\Delta t^3)$ , while the ror in the central difference for v is  $\mathcal{O}(\Delta t^2)$ . The overall error is then no better ian  $\mathcal{O}(\Delta t^2)$ , which can be verified empirically using the convergence\_rates inction from 2.2:

# 9 Generalization: damping, nonlinear sprin external excitation

We shall now generalize the simple model problem from Section 1 to ir possibly nonlinear damping term f(u'), a possibly nonlinear spring (or reforce s(u), and some external excitation F(t):

$$mu'' + f(u') + s(u) = F(t), \quad u(0) = I, \ u'(0) = V, \ t \in (0, T].$$

We have also included a possibly nonzero initial value of u'(0). The par m, f(u'), s(u), F(t), I, V, and T are input data.

There are two main types of damping (friction) forces: linear f(u'): quadratic f(u') = bu'|u'|. Spring systems often feature linear damping air resistance usually gives rise to quadratic damping. Spring forces a linear: s(u) = cu, but nonlinear versions are also common, the most fa the gravity force on a pendulum that acts as a spring with  $s(u) \sim \sin(i)$ 

#### 9.1 A centered scheme for linear damping

Sampling (49) at a mesh point  $t_n$ , replacing  $u''(t_n)$  by  $[D_tD_tu]^n$ , and u  $[D_{2t}u]^n$  results in the discretization

$$[mD_tD_tu + f(D_{2t}u) + s(u) = F]^n,$$

which written out means

$$m\frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2} + f(\frac{u^{n+1} - u^{n-1}}{2\Delta t}) + s(u^n) = F^n,$$

where  $F^n$  as usual means F(t) evaluated at  $t=t_n$ . Solving (51) with re the unknown  $u^{n+1}$  gives a problem: the  $u^{n+1}$  inside the f function may equation nonlinear unless f(u') is a linear function, f(u') = bu'. For shall assume that f is linear in u'. Then

$$m\frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2} + b\frac{u^{n+1} - u^{n-1}}{2\Delta t} + s(u^n) = F^n,$$

which gives an explicit formula for u at each new time level:

$$u^{n+1} = (2mu^n + (\frac{b}{2}\Delta t - m)u^{n-1} + \Delta t^2(F^n - s(u^n)))(m + \frac{b}{2}\Delta t)^{-1}$$

For the first time step we need to discretize u'(0) = V as  $[D_{2t}u = \text{combine with } (53) \text{ for } n = 0$ . The discretized initial condition leads to

$$u^{-1} = u^1 - 2\Delta t V, (54)$$

hich inserted in (53) for n=0 gives an equation that can be solved for  $u^1$ :

$$u^{1} = u^{0} + \Delta t V + \frac{\Delta t^{2}}{2m} (-bV - s(u^{0}) + F^{0}).$$
 (55)

#### .2 A centered scheme for quadratic damping

Then f(u') = bu'|u'|, we get a quadratic equation for  $u^{n+1}$  in (51). This quation can straightforwardly be solved, but we can also avoid the nonlinearity y performing an approximation that is within other numerical errors that we are already committed by replacing derivatives with finite differences.

The idea is to reconsider (49) and only replace u'' by  $D_tD_tu$ , giving

$$[mD_tD_tu + bu'|u'| + s(u) = F]^n, (56)$$

ere, u'|u'| is to be computed at time  $t_n$ . We can introduce a geometric mean, efined by

$$(w^2)^n \approx w^{n-\frac{1}{2}} w^{n+\frac{1}{2}}$$

or some quantity w depending on time. The error in the geometric mean pproximation is  $\mathcal{O}(\Delta t^2)$ , the same as in the approximation  $u'' \approx D_t D_t u$ . With u = u' it follows that

$$[u'|u'|]^n \approx u'(t_n + \frac{1}{2})|u'(t_n - \frac{1}{2})|.$$

he next step is to approximate u' at  $t_{n\pm1/2}$ , but here a centered difference can e used:

$$u'(t_{n+1/2}) \approx [D_t u]^{n+\frac{1}{2}}, \quad u'(t_{n-1/2}) \approx [D_t u]^{n-\frac{1}{2}}.$$
 (57)

le then get

$$[u'|u'|]^n \approx [D_t u]^{n+\frac{1}{2}} |[D_t u]^{n-\frac{1}{2}}| = \frac{u^{n+1} - u^n}{\Lambda t} \frac{|u^n - u^{n-1}|}{\Lambda t}.$$
 (58)

he counterpart to (51) is then

$$m\frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2} + b\frac{u^{n+1} - u^n}{\Delta t} \frac{|u^n - u^{n-1}|}{\Delta t} + s(u^n) = F^n,$$
 (59)

hich is linear in  $u^{n+1}$ . Therefore, we can easily solve with respect to  $u^{n+1}$  and chieve the explicit updating formula

$$u^{n+1} = (m+b|u^n - u^{n-1}|)^{-1} \times (2mu^n - mu^{n-1} + bu^n|u^n - u^{n-1}| + \Delta t^2(F^n - s(u^n))).$$
 (60)

In the derivation of a special equation for the first time step we r some trouble: inserting (54) in (60) for n=0 results in a complicated n equation for  $u^1$ . By thinking differently about the problem we can ear away with the nonlinearity again. We have for n=0 that  $b[u'|u'|]^0$  = Using this value in (56) gives

$$[mD_tD_tu + bV|V| + s(u) = F]^0.$$

Writing this equation out and using (54) results in the special equation first time step:

$$u^{1} = u^{0} + \Delta t V + \frac{\Delta t^{2}}{2m} \left( -bV|V| - s(u^{0}) + F^{0} \right).$$

# 9.3 A forward-backward discretization of the quadamping term

The previous section first proposed to discretize the quadratic dampin |u'|u' using centered differences:  $[|D_{2t}|D_{2t}u]^n$ . As this gives rise to a nonlin  $u^{n+1}$ , it was instead proposed to use a geometric mean combined with a differences. But there are other alternatives. To get rid of the nonline  $[|D_{2t}|D_{2t}u]^n$ , one can think differently: apply a backward difference to [u] that the term involves known values, and apply a forward difference make the term linear in the unknown  $u^{n+1}$ . With mathematics,

$$[\beta|u'|u']^n \approx \beta|[D_t^-u]^n|[D_t^+u]^n = \beta \left|\frac{u^-u^{n-1}}{\Delta t}\right| \frac{u^{n+1}-u^n}{\Delta t}.$$

The forward and backward differences have both an error proportional t one may think the discretization above leads to a first-order scheme. How looking at the formulas, we realize that the forward-backward difference in exactly the same scheme as when we used a geometric mean and c differences. Therefore, the forward-backward differences act in a symme and actually produce a second-order accurate discretization of the qu damping term.

#### 9.4 Implementation

The algorithm arising from the methods in Sections 9.1 and 9.2 is very to the undamped case in Section 1.2. The difference is basically a c of different formulas for  $u^1$  and  $u^{n+1}$ . This is actually quite remarkable equation (49) is normally impossible to solve by pen and paper, but p for some special choices of F, s, and f. On the contrary, the complexit nonlinear generalized model (49) versus the simple undamped model is n deal when we solve the problem numerically!

The computational algorithm takes the form

1. 
$$u^0 = I$$

- 2. compute  $u^1$  from (55) if linear damping or (62) if quadratic damping
- 3. for  $n = 1, 2, \dots, N_t 1$ :
  - (a) compute  $u^{n+1}$  from (53) if linear damping or (60) if quadratic damping

Iodifying the solver function for the undamped case is fairly easy, the big ifference being many more terms and if tests on the type of damping:

```
lef solver(I, V, m, b, s, F, dt, T, damping='linear'):
   Solve m*u'' + f(u') + s(u) = F(t) for t in (0.T].
   u(0)=I and u'(0)=V,
   by a central finite difference method with time step dt.
   If damping is 'linear', f(u')=b*u, while if damping is
   'quadratic', f(u')=b*u'*abs(u').
   F(t) and s(u) are Python functions.
   dt = float(dt): b = float(b): m = float(m) # avoid integer div.
   Nt = int(round(T/dt))
   u = zeros(Nt+1)
   t = linspace(0, Nt*dt, Nt+1)
   u[0] = I
   if damping == 'linear':
       u[1] = u[0] + dt*V + dt**2/(2*m)*(-b*V - s(u[0]) + F(t[0]))
   elif damping == 'quadratic':
       u[1] = u[0] + dt*V + 
              dt**2/(2*m)*(-b*V*abs(V) - s(u[0]) + F(t[0]))
   for n in range(1, Nt):
       if damping == 'linear':
           u[n+1] = (2*m*u[n] + (b*dt/2 - m)*u[n-1] +
                     dt**2*(F(t[n]) - s(u[n])))/(m + b*dt/2)
       elif damping == 'quadratic':
           u[n+1] = (2*m*u[n] - m*u[n-1] + b*u[n]*abs(u[n] - u[n-1])
                     + dt**2*(F(t[n]) - s(u[n])))/
                     (m + b*abs(u[n] - u[n-1]))
   return u, t
```

he complete code resides in the file vib.py<sup>13</sup>.

#### .5 Verification

**Constant solution.** For debugging and initial verification, a constant solution often very useful. We choose  $u_{\rm e}(t)=I$ , which implies V=0. Inserted in the DE, we get F(t)=s(I) for any choice of f. Since the discrete derivative of a postant vanishes (in particular,  $[D_{2t}I]^n=0$ ,  $[D_tI]^n=0$ , and  $[D_tD_tI]^n=0$ ), ie constant solution also fulfills the discrete equations. The constant should herefore be reproduced to machine precision.

**Linear solution.** Now we choose a linear solution:  $u_e = ct + d$ . Th condition u(0) = I implies d = I, and u'(0) = V forces c to be V. In  $u_e = Vt + I$  in the ODE with linear damping results in

$$0 + bV + s(Vt + I) = F(t),$$

while quadratic damping requires the source term

$$0 + b|V|V + s(Vt + I) = F(t).$$

Since the finite difference approximations used to compute u' all are exalinear function, it turns out that the linear  $u_e$  is also a solution of the equations. Exercise 9 asks you to carry out all the details.

Quadratic solution. Choosing  $u_e = bt^2 + Vt + I$ , with b arbitrary the initial conditions and fits the ODE if F is adjusted properly. The salso solves the discrete equations with linear damping. However, this query polynomial in t does not fulfill the discrete equations in case of quadratic decause the geometric mean used in the approximation of this term into an error. Doing Exercise 9 will reveal the details. One can fit  $F^n$  in the equations such that the quadratic polynomial is reproduced by the numethod (to machine precision).

#### 9.6 Visualization

The functions for visualizations differ significantly from those in the uncase in the vib\_undamped.py program because we in the present general not have an exact solution to include in the plots. Moreover, we have estimate of the periods of the oscillations as there will be one period det by the system parameters, essentially the approximate frequency  $\sqrt{}$  for linear s and small damping, and one period dictated by F(t) in excitation is periodic. This is, however, nothing that the program can on or make use of. Therefore, the user has to specify T and the windo in case of a plot that moves with the graph and shows the most recent it in long time simulations.

The vib.py code contains several functions for analyzing the tim signal and for visualizing the solutions.

#### 9.7 User interface

The main function has substantial changes from the vib\_undamped. since we need to specify the new data c, s(u), and F(t). In addition, very set T and the plot window width (instead of the number of periods we simulate as in vib\_undamped.py). To figure out whether we can use of the whole time series or if we should follow the most recent part of the can use the plot\_empricial\_freq\_and\_amplitude function's estimate

<sup>13</sup>http://tinyurl.com/nm5587k/vib/vib.py

umber of local maxima. This number is now returned from the function and sed in main to decide on the visualization technique.

```
lef main():
   import argparse
   parser = argparse.ArgumentParser()
   parser.add_argument('--I', type=float, default=1.0)
   parser.add_argument('--V', type=float, default=0.0)
   parser.add_argument('--m', type=float, default=1.0)
   parser.add_argument('--c', type=float, default=0.0)
   parser.add_argument('--s', type=str, default='u')
   parser.add_argument('--F', type=str, default='0')
   parser.add_argument('--dt', type=float, default=0.05)
   parser.add_argument('--T', type=float, default=140)
   parser.add_argument('--damping', type=str, default='linear')
   parser.add argument('--window width', type=float, default=30)
   parser.add_argument('--savefig', action='store_true')
   a = parser.parse args()
   from scitools.std import StringFunction
   s = StringFunction(a.s, independent variable='u')
   F = StringFunction(a.F. independent variable='t')
   I, V, m, c, dt, T, window_width, savefig, damping = \
      a.I, a.V, a.m, a.c, a.dt, a.T, a.window width, a.savefig, \
      a.damping
   u, t = solver(I, V, m, c, s, F, dt, T)
   num periods = empirical freq and amplitude(u, t)
   if num_periods <= 15:
       figure()
       visualize(u, t)
   else:
       visualize_front(u, t, window_width, savefig)
```

he program vib.py contains the above code snippets and can solve the model roblem (49). As a demo of vib.py, we consider the case  $I=1,\ V=0,\ m=1,\ =0.03,\ s(u)=\sin(u),\ F(t)=3\cos(4t),\ \Delta t=0.05,$  and T=140. The relevant bound to run is

```
ərminal> python vib.py --s '\sin(u)' --F '3*\cos(4*t)' --c 0.03
```

his results in a moving window following the function  $^{14}$  on the screen. Figure 11 nows a part of the time series.

#### .8 The Euler-Cromer scheme for the generalized model

he ideas of the Euler-Cromer method from Section 8 carry over to the generalized nodel. We write (49) as two equations for u and v = u'. The first equation is aken as the one with v' on the left-hand side:

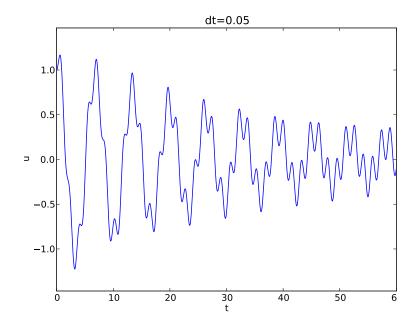

Figure 11: Damped oscillator excited by a sinusoidal function.

$$v' = \frac{1}{m}(F(t) - s(u) - f(v)),$$
  
 $u' = v.$ 

The idea is to step (63) forward using a standard Forward Euler methow we update u from (64) with a Backward Euler method, utilizing the computed  $v^{n+1}$  value. In detail,

$$\frac{v^{n+1} - v^n}{\Delta t} = \frac{1}{m} (F(t_n) - s(u^n) - f(v^n)),$$
$$\frac{u^{n+1} - u^n}{\Delta t} = v^{n+1},$$

resulting in the explicit scheme

$$v^{n+1} = v^n + \Delta t \frac{1}{m} (F(t_n) - s(u^n) - f(v^n)),$$
  
$$u^{n+1} = u^n + \Delta t v^{n+1}.$$

<sup>14</sup>http://tinyurl.com/opdfafk/pub/mov-vib/vib\_generalized\_dt0.05/index.html

/e immediately note one very favorable feature of this scheme: all the nonlinarities in s(u) and f(v) are evaluated at a previous time level. This makes the uler-Cromer method easier to apply and hence much more convenient than the entered scheme for the second-order ODE (49).

The initial conditions are trivially set as

$$v^0 = V, (69)$$

$$u^0 = I. (70)$$

#### 0 Exercises and Problems

#### 'roblem 1: Use linear/quadratic functions for verification

onsider the ODE problem

$$u'' + \omega^2 u = f(t), \quad u(0) = I, \ u'(0) = V, \ t \in (0, T].$$

iscretize this equation according to  $[D_t D_t u + \omega^2 u = f]^n$ .

- ) Derive the equation for the first time step  $(u^1)$ .
- ) For verification purposes, we use the method of manufactured solutions dMS with the choice of  $u_e(x,t) = ct + d$ . Find restrictions on c and d from ne initial conditions. Compute the corresponding source term f by term, how that  $[D_tD_tt]^n = 0$  and use the fact that the  $D_tD_t$  operator is linear,  $D_tD_t(ct+d)]^n = c[D_tD_tt]^n + [D_tD_td]^n = 0$ , to show that  $u_e$  is also a perfect plution of the discrete equations.
- ) Use sympy to do the symbolic calculations above. Here is a sketch of the rogram vib\_undamped\_verify\_mms.py:

```
import sympy as sp
I, t, I, w, dt = sp.symbols('V t I w dt') # global symbols
i = None # global variable for the source term in the ODE
lef ode source term(u):
   """Return the terms in the ODE that the source term
   must balance, here u'' + w**2*u.
   u is symbolic Python function of t."""
   return sp.diff(u(t), t, t) + w**2*u(t)
lef residual discrete eq(u):
   """Return the residual of the discrete eq. with u inserted."""
   return sp.simplify(R)
lef residual_discrete_eq_step1(u):
   """Return the residual of the discrete eq. at the first
   step with u inserted."""
   R = \dots
   return sp.simplify(R)
```

```
def DtDt(u, dt):
    """Return 2nd-order finite difference for u_tt.
    u is a symbolic Python function of t.
    return ...
def main(u):
    Given some chosen solution u (as a function of t, implemented
    as a Python function), use the method of manufactured solutio
    to compute the source term f, and check if u also solves
    the discrete equations.
    print '=== Testing exact solution: %s ===' % u
    print "Initial conditions u(0)=%s, u'(0)=%s:" % \
          (u(t).subs(t, 0), sp.diff(u(t), t).subs(t, 0))
    # Method of manufactured solution requires fitting f
    global f # source term in the ODE
    f = sp.simplify(ode_lhs(u))
    # Residual in discrete equations (should be 0)
    print 'residual step1:', residual_discrete_eq_step1(u)
    print 'residual:', residual_discrete_eq(u)
def linear():
    main(lambda t: V*t + I)
if __name__ == '__main__':
   linear()
```

Fill in the various functions such that the calls in the main function we

- d) The purpose now is to choose a quadratic function  $u_e = bt^2 + ct + d$  solution. Extend the sympy code above with a function quadratic for and checking if the discrete equations are fulfilled. (The function is very to linear.)
- e) Will a polynomial of degree three fulfill the discrete equations?
- f) Implement a solver function for computing the numerical solution problem.
- **g)** Write a nose test for checking that the quadratic solution is comp correctly (too machine precision, but the round-off errors accumulate and with T) by the solver function.

Filenames: vib\_undamped\_verify\_mms.pdf, vib\_undamped\_verify\_mm

#### Exercise 2: Show linear growth of the phase with tin

Consider an exact solution  $I\cos(\omega t)$  and an approximation  $I\cos(\tilde{\omega}t)$ , the phase error as time lag between the peak I in the exact solution corresponding peak in the approximation after m periods of oscillation that this phase error is linear in m. Filename: vib\_phase\_error\_grow

#### exercise 3: Improve the accuracy by adjusting the freuency

ccording to (18), the numerical frequency deviates from the exact frequency by (dominating) amount  $\omega^3 \Delta t^2/24 > 0$ . Replace the w parameter in the algorithm 1 the solver function in vib\_undamped.py by w\*(1 - (1./24)\*w\*\*2\*dt\*\*2 nd test how this adjustment in the numerical algorithm improves the accuracy ise  $\Delta t = 0.1$  and simulate for 80 periods, with and without adjustment of  $\omega$ ). ilename: vib\_adjust\_w.py.

## exercise 4: See if adaptive methods improve the phase er-

daptive methods for solving ODEs aim at adjusting  $\Delta t$  such that the error is ithin a user-prescribed tolerance. Implement the equation u'' + u = 0 in the despy<sup>15</sup> software. Use the example from Section ??in [1]. Run the scheme with very low tolerance (say  $10^{-14}$ ) and for a long time, check the number of time oints in the solver's mesh (len(solver.t\_all)), and compare the phase error ith that produced by the simple finite difference method from Section 1.2 with 100 same number of (equally spaced) mesh points. The question is whether it as off to use an adaptive solver or if equally many points with a simple method ives about the same accuracy. Filename: vib\_undamped\_adaptive.py.

#### Exercise 5: Use a Taylor polynomial to compute $u^1$

s an alternative to the derivation of (8) for computing  $u^1$ , one can use a Taylor olynomial with three terms for  $u^1$ :

$$u(t_1) \approx u(0) + u'(0)\Delta t + \frac{1}{2}u''(0)\Delta t^2$$

/ith  $u'' = -\omega^2 u$  and u'(0) = 0, show that this method also leads to (8). Heneralize the condition on u'(0) to be u'(0) = V and compute  $u^1$  in this case ith both methods. Filename: vib\_first\_step.pdf.

# exercise 6: Find the minimal resolution of an oscillatory unction

ketch the function on a given mesh which has the highest possible frequency. hat is, this oscillatory "cos-like" function has its maxima and minima at very two grid points. Find an expression for the frequency of this function, nd use the result to find the largest relevant value of  $\omega \Delta t$  when  $\omega$  is the equency of an oscillating function and  $\Delta t$  is the mesh spacing. Filename: ib\_largest\_wdt.pdf.

## Exercise 7: Visualize the accuracy of finite difference a cosine function

We introduce the error fraction

$$E = \frac{[D_t D_t u]^n}{u''(t_n)}$$

to measure the error in the finite difference approximation  $D_t D_t u$  to u''. C E for the specific choice of a cosine/sine function of the form  $u = \exp(i \sinh u)$ 

$$E = \left(\frac{2}{\omega \Delta t}\right)^2 \sin^2(\frac{\omega \Delta t}{2}).$$

Plot E as a function of  $p = \omega \Delta t$ . The relevant values of p are  $[0, \pi]$  (see Exforming the formula of the curve from unalized the error in the approximation. Also expand E as a Taylor polynomia up to fourth degree (use, e.g., sympy). Filename: vib\_plot\_fd\_exp\_er

#### Exercise 8: Verify convergence rates of the error in e

We consider the ODE problem  $u'' + \omega^2 u = 0$ , u(0) = I, u'(0) = V, for t The total energy of the solution  $E(t) = \frac{1}{2}(u')^2 + \frac{1}{2}\omega^2 u^2$  should stay c The error in energy can be computed as explained in Section 7.

Make a nose test in a file test\_error\_conv.py, where code from vib\_ is imported, but the convergence\_rates and test\_convergence\_rat tions are copied and modified to also incorporate computations of the energy and the convergence rate of this error. The expected rate is 2. F test\_error\_conv.py.

#### Exercise 9: Use linear/quadratic functions for verific

This exercise is a generalization of Problem 1 to the extended model I (49) where the damping term is either linear or quadratic. Solve the subproblems and see how the results and problem settings change w generalized ODE in case of linear or quadratic damping. By modify code from Problem 1, sympy will do most of the work required to anal generalized problem. Filename: vib\_verify\_mms.py.

#### Exercise 10: Use an exact discrete solution for verific

Write a nose test function in a separate file that employs the exact solution (19) to verify the implementation of the solver function in vib\_undamped.py. Filename: test\_vib\_undamped\_exact\_discrete\_s

<sup>15</sup>https://github.com/hplgit/odespy

#### 

he purpose of this exercise is to perform convergence tests of the problem (49) hen  $s(u) = \omega^2 u$  and  $F(t) = A \sin \phi t$ . Find the complete analytical solution to ne problem in this case (most textbooks on mechanics or ordinary differential quations list the various elements you need to write down the exact solution). In lodify the convergence\_rate function from the vib\_undamped.py program to erform experiments with the extended model. Verify that the error is of order  $t^2$ . Filename: vib\_conv\_rate.py.

#### exercise 12: Investigate the amplitude errors of many solvers

se the program vib\_undamped\_odespy.py from Section 6 and the ampliide estimation from the amplitudes function in the vib\_undamped.py file
ee Section 3.4) to investigate how well famous methods for 1st-order ODEs
an preserve the amplitude of u in undamped oscillations. Test, for example,
ie 3rd- and 4th-order Runge-Kutta methods (RK3, RK4), the Crank-Nicolson
iethod (CrankNicolson), the 2nd- and 3rd-order Adams-Bashforth methods
idamsBashforth2, AdamsBashforth3), and a 2nd-order Backwards scheme
Backward2Step). The relevant governing equations are listed in Section 22.
ilename: vib\_amplitude\_errors.py.

#### Exercise 13: Minimize memory usage of a vibration solver

he program vib.py<sup>16</sup> store the complete solution  $u^0, u^1, \ldots, u^{N_t}$  in memory, hich is convenient for later plotting. Make a memory minimizing version of his program where only the last three  $u^{n+1}$ ,  $u^n$ , and  $u^{n-1}$  values are stored hemory. Write each computed  $(t_{n+1}, u^{n+1})$  pair to file. Visualize the data the file (a cool solution is to read one line at a time and plot the u value sing the line-by-line plotter in the visualize\_front\_ascii function - this echnique makes it trivial to visualize very long time simulations). Filename: ib\_memsave.py.

#### Exercise 14: Implement the solver via classes

eimplement the vib.py program using a class Problem to hold all the physical arameters of the problem, a class Solver to hold the numerical parameters and ompute the solution, and a class Visualizer to display the solution.

**lint.** Use the ideas and examples from Section ?? and ??in [1]. More specifially, make a superclass Problem for holding the scalar physical parameters of a roblem and let subclasses implement the s(u) and F(t) functions as methods. ry to call up as much existing functionality in vib.py as possible. ilename: vib class.py.

#### 16http://tinyurl.com/nm5587k/vib/vib.py

Show that the difference  $[D_tD_tu]^n$  is equal to  $[D_t^+D_t^-u]^n$  and  $D_t^-D_t^+u]$  is, instead of applying a centered difference twice one can alternatively mixture forward and backward differences. Filename:  $vib_DtDt_fw_bw$ 

# Exercise 16: Use the forward-backward scheme with q damping

We consider the generalized model with quadratic damping, express system of two first-order equations as in Section ??:

$$u' = v,$$
  
$$v' = \frac{1}{m} \left( F(t) - \beta |v| v - s(u) \right).$$

However, contrary to what is done in Section ??, we want to apply the the forward-backward discretization in Section 8. Express the idea in  $\mathfrak c$  notation and write out the scheme. Unfortunately, the backward differ the v equation creates a nonlinearity  $|v^{n+1}|v^n$ . To linearize this nonlinea the known value  $v^n$  inside the absolute value factor, i.e.,  $|v^{n+1}|v^n \approx |v^n|$ . Show that the resulting scheme is equivalent to the one in Section ?? If time level n > 1.

What we learn from this exercise is that the first-order differences linearization trick play together in "the right way" such that the schen good as when we (in Section ??) carefully apply centered difference geometric mean on a staggered mesh to achieve second-order accuracy. 'a difference in the handling of the initial conditions, though, as explaine end of Section 8. Filename: vib gen bwdamping.pdf.

## Exercise 17: Use a backward difference for the dar term

As an alternative to discretizing the damping terms  $\beta u'$  and  $\beta |u'|u'$  by  $\epsilon$  differences, we may apply backward differences:

$$[u']^n \approx [D_t^- u]^n,$$
  
 $[|u'|u']^n \qquad \approx [|D_t^- u|D_t^- u]^n = |[D_t^- u]^n|[D_t^- u]^n.$ 

The advantage of the backward difference is that the damping term i ated using known values  $u^n$  and  $u^{n-1}$  only. Extend the vib.py<sup>17</sup> co a scheme based on using backward differences in the damping term

<sup>17</sup>http://tinyurl.com/nm5587k/vib/vib.pv

catements to compare the original approach with centered difference and the ew idea launched in this exercise. Perform numerical experiments to investigate ow much accuracy that is lost by using the backward differences. Filename: ib\_gen\_bwdamping.pdf.

#### exercise 18: Simulate a bouncing ball

bouncing ball is a body in free vertically fall until it impacts the ground. uring the impact, some kinetic energy is lost, and a new motion upwards with educed velocity starts. At some point the velocity close to the ground is so nall that the ball is considered to be finally at rest.

The motion of the ball falling in air is governed by Newton's second law ' = ma, where a is the acceleration of the body, m is the mass, and F is the 1m of all forces. Here, we neglect the air resistance so that gravity -mg is the 1nly force. The height of the ball is denoted by h and v is the velocity. The elations between h, v, and a,

$$h'(t) = v(t), \quad v'(t) = a(t),$$

ombined with Newton's second law gives the ODE model

$$h''(t) = -g, (71)$$

r expressed alternatively as a system of first-order equations:

$$v'(t) = -g, (72)$$

$$h'(t) = v(t). (73)$$

hese equations govern the motion as long as the ball is away from the ground y a small distance  $\epsilon_h > 0$ . When  $h < \epsilon_h$ , we have two cases.

- 1. The ball impacts the ground, recognized by a sufficiently large negative velocity  $(v < -\epsilon_v)$ . The velocity then changes sign and is reduced by a factor  $C_R$ , known as the coefficient of restitution<sup>18</sup>. For plotting purposes, one may set h = 0.
- 2. The motion stops, recognized by a sufficiently small velocity ( $|v| < \epsilon_v$ ) close to the ground.

hoose one of the models, (71) or (72)-(73), and simulate a bouncing ball. Plot (t). Think about how to plot v(t).

**lint.** A naive implementation may get stuck in repeated impacts for large me step sizes. To avoid this situation, one can introduce a state variable that olds the mode of the motion: free fall, impact, or rest. Two consecutive impacts nply that the motion has stopped.

ilename: bouncing\_ball.py.

18http://en.wikipedia.org/wiki/Coefficient\_of\_restitution

#### Exercise 19: Simulate an elastic pendulum

Consider an elastic pendulum fixed to the point  $\mathbf{r}_0 = (0, L_0)$ . The let the pendulum wire when not stretched is  $L_0$ . The wire is massless and straight. At the end point  $\mathbf{r}$ , we have a mass m. Stretching the elastic distance s gives rise to a spring force ks in the opposite direction of the structure  $\mathbf{r}$  be a unit normal vector along the wire:

$$m{n} = rac{m{r} - m{r}_0}{||m{r} - m{r}_0||}$$
 .

The stretch s in the wire is the current length  $||r - r_0||$  at some time the original length  $L_0$ :

$$s = ||\boldsymbol{r} - \boldsymbol{r}_0|| - L_0.$$

The force in the wire is then  $F_w = -ksn$ . Newton's second law of motion to the mass results in

$$m\ddot{r} = -ksn - mgj$$

where j is a unit vector in the upward vertical direction. Let  $r = (x n = (n_x, n_y))$ . The two components of (74) then becomes

$$\ddot{x} = -m^{-1}ksn_x.$$

$$\ddot{y} = -m^{-1}ksn_y - g.$$

The mass point (x, y) will undergo a two-dimensional motion, but if the stiff (large k), the elastic pendulum will approach the classical one who mass point moves along a circle. However, the elastic pendulum is r by a direct application of Newton's second law, because the force in t is known (as a function of the motion), while the classical pendulum is constrained motion, which requires elimination of an unknown via the co (by invoking polar coordinates).

In equilibrium, the mass hangs in the position  $(0, y_0)$  determined by

$$0 = -m^{-1}ksn_y - g = m^{-1}k(y_0 - L_0) - g \quad \Rightarrow \quad y_0 = L_0 + mg/k = 0$$

We then displace the mass an angle  $\theta_0$  to the right. The initial position (x( then becomes

$$x(0) = L \sin \theta_0, \quad y(0) = L_0 - L \cos \theta_0.$$

The velocity is zero, x'(0) = y'(0) = 0.

) Write a code that can simulate such an elastic pendulum. Plot y against x in plot with the same length scale on the axis such that we get a correct picture f the motion. Also plot the angle the pendulum:  $\theta = \tan^{-1} x/(L_0 - y)$ .

A possible set of parameters is  $L_0 = 9.81$  m, m = 1 kg,  $theta_0 = 30$  degrees.

**lint 1.** The associated classical pendulum, for large k, has an equation  $+ g/L_0\theta = 0$ . With  $g = L_0$ , the period is  $2\pi$ :  $\theta(t) = \theta_0 \cos(t)$ . One can ompare in a plot the angle of the elastic solution  $(\theta = \tan^{-1} x/(L_0 - y))$  with ne solution of the classical pendulum problem.

lint 2. The equation of motion is subject to round-off errors for large k, ecause s is then small such that ks is a product of a large and a small number. In loreover, in this stiff case,  $m^{-1}ksn_y$  is close to g such that we also subtract vo almost equal numbers in the force term in the equation. For the given arameters, k=150 is a large value and gives a solution close to the motion of perfect classical pendulum. Much larger values gives unstable solutions.

) Air resistance is a force  $\frac{1}{2}\varrho C_D A||bmv||v$ , where  $C_D$  is a drag coefficient (0.2 r a sphere),  $\varrho$  is the density of air (1.2 kg m<sup>-3</sup>), A is the cross section area  $A = \pi R^2$  for a sphere, where R is the radius), and v is the velocity:  $v = \dot{r}$ . Include air resistance in the model and show plots comparing the motion with and without air resistance.

ilename: elastic\_pendulum.py.

#### exercise 20: Analysis of the Euler-Cromer scheme

he Euler-Cromer scheme for the model problem  $u'' + \omega^2 u = 0$ , u(0) = I, '(0) = 0, is given in (44)-(43). Find the exact discrete solutions of this scheme and show that the solution for  $u^n$  coincides with that found in Section 4.

**lint.** Use an "ansatz"  $u^n = I \exp(i\tilde{\omega}\Delta t n)$  and  $v^=qu^n$ , where  $\tilde{\omega}$  and q are nknown parameters. The formula

$$\exp\left(i\tilde{\omega}(\Delta t)\right) + \exp\left(i\tilde{\omega}(-\Delta t)\right) - 2 = 2\left(\cosh(i\tilde{\omega}\Delta t) - 1\right) = -4\sin^2(\frac{\tilde{\omega}\Delta t}{2}),$$

ecomes handy.
